Vascular malformations are localized defects of vascular morphogenesis, likely caused by dysfunction in pathways regulating the angiogenesis. According to the classification system adopted by the International Society for the Study of Vascular Anomalies (ISSVA), vascular malformations are categorized as capillary, venous, lymphatic and arteriovenous, depending on the predominant type(s) of anomalous vessels. Categorizing a lesion as a capillary malformations (CM), venous malformations (VM), lymphatic malformations (LM), arteriovenous malformations (AVM), or combined lesion is important, since the prognosis and the treatment differ depending on the type(s) of vessels involved.1,2 However, small vascular malformations of the lip can pose difficult diagnostic challenges, due to their parallel natural history and clinical similarities (Fig.s 1,2).

The detection of some specific features may facilitate the diagnosis and allow the distinction between VM and AVM. Venous malformations typically present as slow-growing, soft, compressible, blue to violaceous nodules, that are usually asymptomatic and have tendency to fill with Valsalva maneuver or dependent position. Dermoscopic assessment of this lesions commonly shows the presence of clods and a structureless pattern that may vary in color.3 In contrast, arteriovenous malformations of the lip can pose difficult diagnostic challenges, due to their parallel natural history and clinical similarities (Fig.s 1,2).

Venous and Arteriovenous Malformations of the Lip:
A Problematic Differential Diagnosis

KEY WORDS – Arteriovenous Malformations; Lip; Vascular Malformations.
